

## Cryptographic Protocols

### Solution to Exercise 3

#### 3.1 Geometric Zero-Knowledge

- a) Given two angles  $\alpha$  and  $\beta$ , the angle  $\alpha \pm \beta$  can be constructed as follows: Open the compass to an arbitrary angle. Draw a circle around the endpoints of both angles with the resulting radius, which results in four new points  $p_\alpha, p'_\alpha, p_\beta, p'_\beta$ . Open the compass to the distance between  $p_\alpha$  and  $p'_\alpha$ . Draw a circle around, say,  $p_\beta$  with the resulting radius and create the line  $\ell$  through  $p_\beta$  and  $p'_\beta$  as well as the intersection points  $q_\beta$  and  $q'_\beta$  of the circle and  $\ell$ . Then, create a line through the endpoint of  $\beta$  and  $q_\beta$  or  $q'_\beta$ , depending on whether  $\alpha + \beta$  or  $\alpha - \beta$  is to be constructed.
- b) A possible protocol for this task is the following one:

Peggy		Vic
knows angles $\alpha, \beta$ s.t. $\beta = 3\alpha$		knows angle $\beta$
choose random angle $\kappa$ create $\tau := 3\kappa$	$\xrightarrow{\tau}$	
	$\xleftarrow{c}$	choose random $c \in_R \{0, 1\}$
create $\rho := \kappa + c\alpha$	$\xrightarrow{\rho}$	check $3\rho \stackrel{?}{=} \tau + c\beta$

- c) **COMPLETENESS:** One can easily verify that if Peggy is honest and knows  $\alpha$ , Vic will always accept.

**SOUNDNESS (PROOF OF KNOWLEDGE):** Here we show that if Peggy knows how to answer both challenges, she actually can compute the trisection  $\alpha$ . Assume Peggy knows successful answers  $\rho, \rho'$  to both challenges  $c = 0$  and  $c' = 1$  for the same first message  $\tau$ . In that case,

$$3\rho = \tau \quad \text{and} \quad 3\rho' = \tau + \beta.$$

Thus,  $3\rho' - 3\rho = \beta = 3\alpha$ , and, therefore, Peggy may compute the angle  $\alpha$  as  $\rho' - \rho$ .

- d) **ZERO-KNOWLEDGE:** The protocol is  $c$ -simulatable: for a given challenge  $c \in \{0, 1\}$ , choose a uniform random angle  $\rho$  and set  $\tau := 3\rho - c\beta$ , which is easily checked to result in the correct distribution. Moreover, the size of the challenge space is clearly polynomial.

#### 3.2 Honest-Verifier Zero-Knowledge and $c$ -Simulatability

Let  $(P, V)$  be a HVZK protocol for  $R$ . Let  $x$  be the instance. A protocol  $(P', V')$  for  $R$  can be the following:

1.  $P'$  computes the first message  $t$  using  $P$ , and also chooses a random challenge  $c'' \in \mathcal{C}$ . Send  $t' := (t, c'')$  to  $V'$ .

2.  $V'$  chooses a random challenge  $c' \in \mathcal{C}$  and sends it to  $P'$ .
3.  $P'$  computes  $c = c' + c''$ , and a valid answer  $r$  to  $c$  using  $P$ . Send  $r' := r$  to  $V'$ .
4.  $V'$  checks if  $(t, c' + c'', r)$  is an accepting transcript for the instance  $x$  using  $V$ , and accepts/rejects accordingly.

The idea is that the new protocol  $(P', V')$  is the same as  $(P, V)$ , but the challenge is the XOR of challenges chosen by  $P'$  and  $V'$ .

**COMPLETENESS:** It is easy to verify that the protocol is complete, because the protocol  $(P, V)$  is complete.

**SOUNDNESS (PROOF OF KNOWLEDGE):** In this proof we assume that the protocol  $(P, V)$  is 2-extractable. That is, that from two accepting triples  $(t, c_1, r_1)$  and  $(t, c_2, r_2)$  one can extract the witness. Then, the protocol  $(P', V')$  is also sound. Let  $((t, c''), c'_1, r'_1)$ ,  $((t, c''), c'_2, r'_2)$  be two accepting triples in protocol  $(P', V')$ . This means that  $(t, c'' + c'_1, r'_1)$  and  $(t, c'' + c'_2, r'_2)$  are two accepting triples in  $(P, V)$  and one can extract the witness  $w$  from the two triples.

**C-SIMULATABLE:** The protocol is  $c$ -simulatable, because, given  $c'$ , one can invoke the HVZK simulator for  $(P, V)$  which returns  $(t, c, r)$ , and can choose  $c'' = c + c'$ , and set  $(t', r') = ((t, c''), r)$ . Then, the triple  $(t', c', r')$  is identically distributed as in the protocol  $(P', V')$ , conditioned on the challenge being  $c'$ .

### 3.3 An Interactive Proof

a) A possible protocol, similar to Schnorr's protocol, is the following:

**COMPLETENESS:** It is easily verified that if Peggy is honest and knows  $(x, y)$ , then Vic always accepts.

**SOUNDNESS (PROOF OF KNOWLEDGE):** From the prover's replies to two different challenges for the same first message  $t$ , one can compute values  $x'$  and  $y'$  such that  $g^{x'} h^{y'} = z$ : Let  $(t, c, (r, s))$  and  $(t, c', (r', s'))$  be two accepting transcripts with  $c \neq c'$ . That is,  $g^r h^s = tz^c$  and  $g^{r'} h^{s'} = tz^{c'}$ . By dividing the first equation by the second one we get:

$$g^{r-r'} h^{s-s'} = z^{c-c'} = (g^x h^y)^{c-c'},$$

which implies that  $x' = (r - r')(c - c')^{-1}$  and  $y' = (s - s')(c - c')^{-1}$  are values with  $g^{x'} h^{y'} = z$ . Note that since  $|G|$  is prime,  $c - c' \neq 0$  has an inverse modulo  $|G|$ .

b) **ZERO-KNOWLEDGE:** Similarly to all previous examples, the protocol is  $c$ -simulatable: Choose random  $r, s \in \mathbb{Z}_{|G|}$  and set  $t := g^r h^s z^{-c}$ , which is easily checked to result in the correct distribution. If  $\mathcal{C}$  is chosen to be polynomially large, the protocol is zero-knowledge.
